10-601 Machine Learning

Decision trees

Types of classifiers

- We can divide the large variety of classification approaches into roughly two main types
 - 1. Instance based classifiers
 - Use observation directly (no models)
 - e.g. K nearest neighbors
 - 2. Generative:
 - build a generative statistical model
 - e.g., Bayesian networks
 - 3. Discriminative
 - directly estimate a decision rule/boundary
 - e.g., decision tree

Decision trees

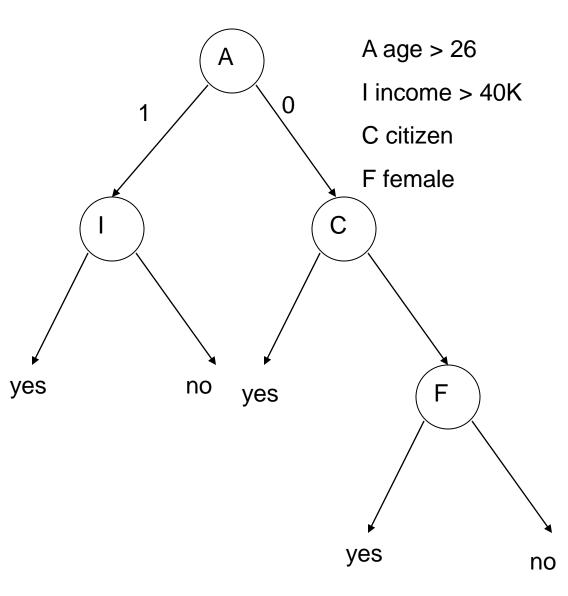

- One of the most intuitive classifiers
- Easy to understand and construct
- Surprisingly, also works very (very) well*

Lets build a decision tree!

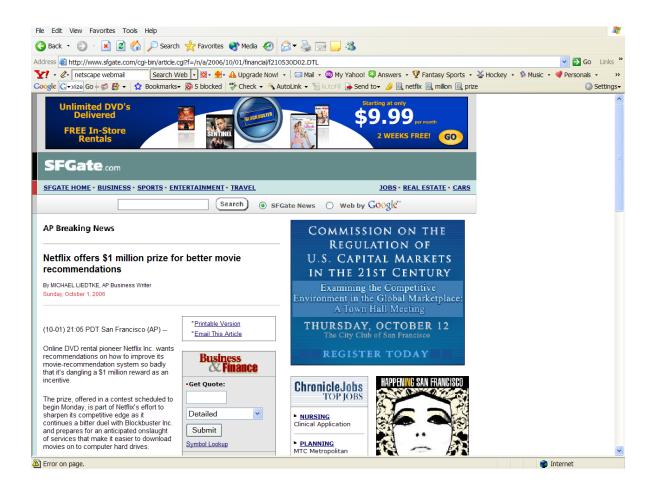

^{*} More on this towards the end of this lecture

Structure of a decision tree

- Internal nodes correspond to attributes (features)
- Leafs correspond to classification outcome
- edges denote assignment

Building a decision tree

```
Function BuildTree(n,A) // n: samples (rows), A: attributes
 If empty(A) or all n(L) are the same
    status = leaf
    class = most common class in n(L)
 else
    status = internal
    a \leftarrow bestAttribute(n,A)
    LeftNode = BuildTree(n(a=1), A \ {a})
    RightNode = BuildTree(n(a=0), A \ {a})
  end
end
```

Building a decision tree

```
Function BuildTree(n,A) // n: samples (rows), A: attributes
 If empty(A) or all n(L) are the same
                                               n(L): Labels for samples in
    status = leaf
                                               this set
    class = most common class in n(L)
 else
                                               We will discuss this function
    status = internal
                                                next
    a \leftarrow bestAttribute(n,A)
    LeftNode = BuildTree(n(a=1), A \ \{a\})
                                                   Recursive calls to create left
                                                  and right subtrees, n(a=1) is
    RightNode = BuildTree(n(a=0), A \ {a})
                                                  the set of samples in n for
  end
                                                  which the attribute a is 1
end
```

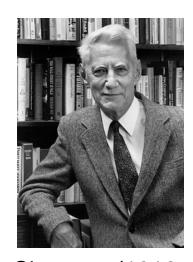

Identifying 'bestAttribute'

- There are many possible ways to select the best attribute for a given set.
- We will discuss one possible way which is based on information theory and generalizes well to non binary variables

Entropy

- Quantifies the amount of uncertainty associated with a specific probability distribution
- The higher the entropy, the less confident we are in the outcome
- Definition

$$H(X) = \sum_{c} -p(X = c) \log_2 p(X = c)$$

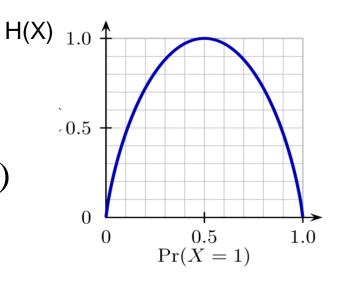

Claude Shannon (1916 – 2001), most of the work was done in Bell labs

Entropy

Definition

$$H(X) = \sum_{i} -p(X = i) \log_2 p(X = i)$$

• So, if P(X=1) = 1 then

$$H(X) = -p(x=1)\log_2 p(X=1) - p(x=0)\log_2 p(X=0)$$

= -1\log 1 - 0\log 0 = 0

• If P(X=1) = .5 then

$$H(X) = -p(x=1)\log_2 p(X=1) - p(x=0)\log_2 p(X=0)$$
$$= -.5\log_2 .5 - .5\log_2 .5 = -\log_2 .5 = 1$$

Interpreting entropy

- Entropy can be interpreted from an information standpoint
- Assume both sender and receiver know the distribution.
 How many bits, on average, would it take to transmit one value?
- If P(X=1) = 1 then the answer is 0 (we don't need to transmit anything)
- If P(X=1) = .5 then the answer is 1 (either values is equally likely)
- If 0<P(X=1)<.5 or 0.5<P(X=1)<1 then the answer is between 0 and 1
 - Why?

Expected bits per symbol

- Assume P(X=1) = 0.8
- Then P(11) = 0.64, P(10)=P(01)=.16 and P(00)=.04
- Lets define the following code
 - For 11 we send 0
 - For 10 we send 10
 - For 01 we send 110
 - For 00 we send 1110

Expected bits per symbol

- Assume P(X=1) = 0.8
- Then P(11) = 0.64, P(10)=P(01)=.16 and P(00)=.04
- Lets define the following code
 - For 11 we send 0
 - For 10 we send 10
 - For 01 we send 110
 - For 00 we send 1110

so: 01001101110001101110

can be broken to: 01 00 11 01 11 00 01 10 11 10

which is: 110 1110 0 110 0 1110 110 10 0 10

- What is the expected bits / symbol? (.64*1+.16*2+.16*3+.04*4)/2 = 0.8
- Entropy (lower bound) H(X)=0.7219

Conditional entropy

- Entropy measures the uncertainty in a specific distribution
- What if both sender and receiver know something about the transmission?
- For example, say I want to send the label (liked) when the length is known
- This becomes a conditional entropy problem: H(Li | Le=v)

Is the entropy of Liked among movies with length v

Conditional entropy: Examples for specific values

- We can generalize the conditional entropy idea to determine H(Li | Le)
- That is, what is the expected number of bits we need to transmit if both sides know the value of Le for each of the records (samples)
- Definition: $H(X | Y) = \sum_{i} P(Y = i)H(X | Y = i)$

We explained how to compute this in the previous slides

Conditional entropy: Example

Movie length	Liked?
Short	Yes

$$H(X \mid Y) = \sum_{i} P(Y = i)H(X \mid Y = i)$$

Lets compute H(Li | Le)

we already computed:

$$H(Li | Le = S) = .92$$

$$H(Li \mid Le = M) = 0$$

$$H(Li \mid Le = L) = .92$$

Information gain

- How much do we gain (in terms of reduction in entropy) from knowing one of the attributes
- In other words, what is the reduction in entropy from this knowledge
- Definition: IG(X|Y)* = H(X)-H(X|Y)

Where we are

- We were looking for a good criteria for selecting the best attribute for a node split
- We defined the entropy, conditional entropy and information gain
- We will now use information gain as our criteria for a good split
- That is, BestAttribute will return the attribute that maximizes the information gain at each node

Building a decision tree

```
Function BuildTree(n,A) // n: samples (rows), A: attributes
 If empty(A) or all n(L) are the same
    status = leaf
    class = most common class in n(L)
 else
                                              Based on information gain
    status = internal
    a \leftarrow bestAttribute(n,A)
    LeftNode = BuildTree(n(a=1), A \ {a})
    RightNode = BuildTree(n(a=0), A \ {a})
  end
end
```

P(Li=yes) = 2/3

H(Li) = .91

 $H(Li \mid T) =$

 $H(Li \mid Le) =$

 $H(Li \mid D) =$

H(Li | F) =

We only need to focus on the records (samples) associated with this node

We eliminated the 'director' attribute. All samples have the same director

Additional points

- The algorithm we gave reaches homogonous nodes (or runs out of attributes)
- This is dangerous: For datasets with many (non relevant) attributes the algorithm will continue to split nodes
- This will lead to overfitting!

Avoiding overfitting: Tree pruning

- Split data into train and test set
- Build tree using training set
 - For all internal nodes (starting at the root)
 - remove sub tree rooted at node
 - assign class to be the most common among training set
 - check test data error
 - if error is lower, keep change
 - otherwise restore subtree, repeat for all nodes in subtree

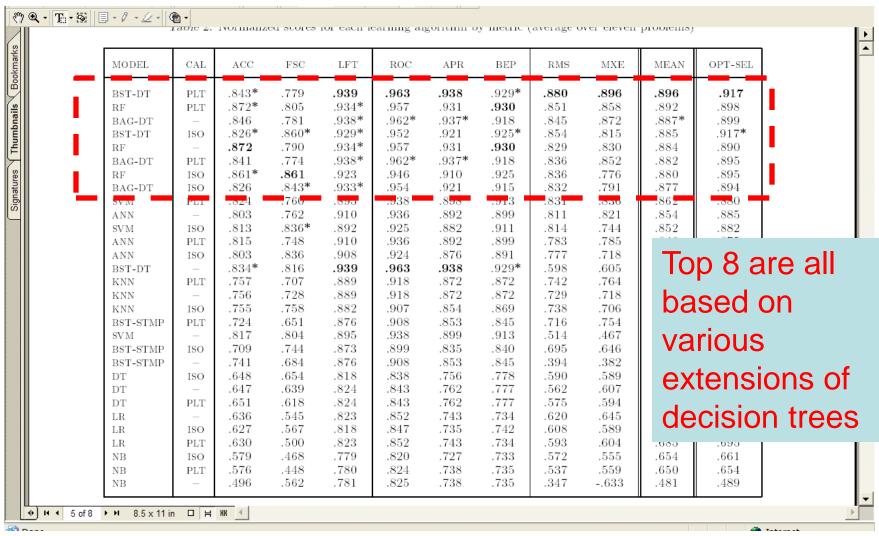

Continuous values

- Either use threshold to turn into binary or discretize
- Its possible to compute information gain for all possible tresholds (there are a finite number of training samples)
- Harder if we wish to assign more than two values (can be done recursively)

The 'best' classifier

- There has been a lot of interest lately in decision trees.
- They are quite robust, intuitive and, surprisingly, very accurate

Ranking classifiers

Rich Caruana & Alexandru Niculescu-Mizil, An Empirical Comparison of Supervised Learning Algorithms, ICML 2006

Important points

- Discriminative classifiers
- Entropy
- Information gain
- Building decision trees

Random forest

- A collection of decision trees
- For each tree we select a subset of the attributes (recommended square root of |A|) and build tree using just these attributes
- An input sample is classified using majority voting
